### Introduction

Carbon-dioxide (CO<sub>2</sub>)<sup>1</sup> transmitters are gaining popularity in building HVAC systems to monitor indoor air CO<sub>2</sub> concentration and to control the outdoor air intake rate.

Controlling ventilation air flow rates using CO<sub>2</sub>-based Demand Controlled Ventilation (DCV) offers the possibility of reducing the energy penalty associated with over-ventilation during periods of low occupancy, while still ensuring adequate levels of outdoor air ventilation (Emmerich and Persily 2001). A report prepared for DOE (Roth et al. 2005) suggests that DCV can reduce both heating and cooling energy by about 10% or about 0.3 quadrillion BTUs annually.

In CO<sub>2</sub>-based DCV systems, the CO<sub>2</sub> level of indoor air is monitored and the outdoor air flow rate is adjusted based on the transmitter output to maintain acceptable CO<sub>2</sub> concentration in the occupied space. The performance of CO<sub>2</sub> transmitters is crucial in this control process. A general guideline often used in DCV is that the CO<sub>2</sub> concentration in a space should not exceed 700 ppm above the ambient CO<sub>2</sub> level. For occupants involved in sedentary activities (such as in an office or classroom) this corresponds to approximately 15 cfm of outdoor air per person. Transmitters which read high will call for more outdoor air resulting in an energy penalty. A transmitter which reads 100 ppm high would result in approximately 17% more ventilation air flow. Transmitters which read low could cause poor indoor air quality. CO<sub>2</sub> transmitters are reported to have technology-specific sensitivities, and unresolved issues including drift, overall accuracy, temperature effect, water vapor, dust buildup, and aging of the light sources etc. (Dougan and Damiano 2004).

Because of their impact on energy usage and indoor air quality, the National Building Controls Information Program (NBCIP) tested and evaluated the performance of Non-Dispersive Infrared (NDIR) wall-mounted CO<sub>2</sub> transmitters used in typical building HVAC applications. NBCIP developed an experimental procedure for testing the CO<sub>2</sub> transmitters, and used this procedure to test fifteen models of CO<sub>2</sub> transmitters.

This NBCIP Product Testing Report provides an overview of factors to consider when purchasing a CO<sub>2</sub> transmitter, presents manufacturer data for transmitters selected for testing, describes the test procedure and test apparatus used by NBCIP to evaluate transmitter performance, and presents test results for accuracy, linearity, hysteresis, repeatability, humidity sensitivity, temperature sensitivity, and pressure sensitivity for each CO<sub>2</sub> transmitter model tested.

<sup>1</sup> Throughout this report, the CO<sub>2</sub> sensing element is referred to as the sensor. A CO<sub>2</sub> transmitter is a device that consists of a sensor as well as a transducer that converts the sensor reading into an output signal.

# Conclusions

The result from the tests conducted under accurate and repeatable conditions showed a wide variation in transmitter performance among the fifteen NDIR CO<sub>2</sub> transmitter models. In some cases, significant variations in transmitter performance exist between transmitters of the same model while in other cases, all transmitters of the same model showed almost identical behavior.

None of the transmitter models meet their manufacturer specified accuracy statement for all three transmitters of a given model over the full range of test conditions. For some models, none of the transmitters meet the accuracy specifications over the range. Table 12 summarizes the transmitter models and the number of transmitters of the given model that meet the manufacturer’s accuracy statement for the model. It is important to note that there is a wide variation in accuracy statements among the manufacturers, and the results presented in the table are not an indication of the performance between the various transmitter models.

Given the test results and that the transmitters were tested under “as received” conditions, it appears that transmitter calibration should be performed before putting a transmitter into service.

However, for transmitters with an automatic baseline adjustment algorithm, it is impossible to predict the transmitter’s performance over a prolonged time period during which the transmitter baseline might make multiple adjustments. In fact, the product data for several transmitter models that incorporate an automatic baseline adjustment algorithm claim that the transmitters do not require calibration. Given the transmitter is “self adjusting” using an arbitrary baseline reading of 400 ppm, it is unclear how the transmitter manufacturer can claim an absolute accuracy for their transmitter. However, some of the models that utilize automatic baseline adjustment algorithm do appear to be “accurate” if one accounts for the bias created by the baseline adjustment. For example, all three AirTest Technologies TR9290 transmitters (Figure 9a) would perform as specified if the transmitter readings were adjusted downward by approximately 50 ppm. The same is true for several other non self-adjusting transmitters that show a relatively constant value of deviation as the CO<sub>2</sub> concentration is increased. For transmitters that show increasingly larger values of deviation as the CO<sub>2</sub> concentration increases (see Figure 9g), a simple bias adjustment would not make the transmitter reading accurate over the full range of CO<sub>2</sub> concentrations.

Table 12. CO<sub>2</sub> Transmitter accuracy summary.

| Manufacturer                  | Model Number   | All 3 transmitters meet the manufacturer’s accuracy statement | 2 transmitters meet the manufacturer’s accuracy statement | 1 transmitter meets the manufacturer’s accuracy statement | None of the transmitters meet the manufacturer’s accuracy statement |

Notes:

1. The information in this table was obtained first from the product data supplied with the transmitters, or next from the product documents available on the mfg web site, or last from the mfg web page.
2. NA indicates that the information was not available in the manufacturer's product literature.
3. NBCIP tested the wall-mounted carbon dioxide transmitters using a supply voltage of 24 VDC or 24VAC as specified by manufacturers.
4. NBCIP tested the wall-mounted carbon dioxide transmitters using VDC output. Current output from Honeywell transmitters was converted to VDC using 1% 250-ohm resistors.
5. None of the manufacturers reported humidity sensitivity of their transmitters.
